Lecture 11: Computational Efficiency

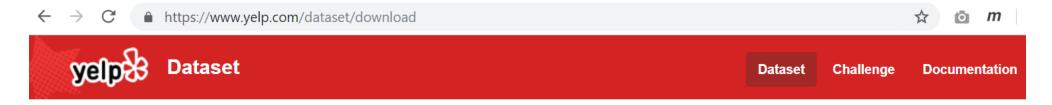

LING 1340/2340: Data Science for Linguists
Na-Rae Han

Objectives

- Big data considerations
- Computational efficiency
 - Memory vs. processing time
 - Algorithmic complexity
 - Big O notation
- Word embeddings
 - Dan's presentation

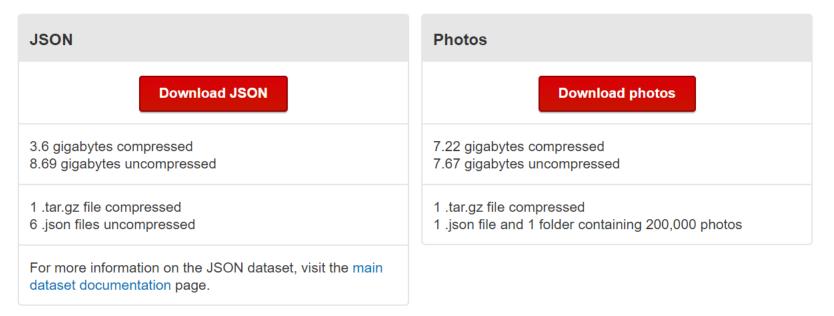

The Yelp Dataset Challenge

https://www.yelp.com/dataset/challenge

Download The Data

The links to download the data will be valid for 30 seconds.

Working with big data files

```
naraehan@login0:/zfs2/ling1340-2019s/shared_data/yelp_dataset_13
[naraehan@login0 yelp_dataset_13]$ ls -lah
total 5.1G
drwxr-xr-x 2 naraehan ling1340-2019s   10 Mar 21 12:03 .

```

Opening + processing big files

▶ How much resource does it take to process review.json file (5.0GB)?

Memory consideration

▶ How much space needed for bigrams? Trigrams?

Good news! These are built as generator objects and take up almost zero space.

```
process_reviews2.py - C:/Users/narae/Documents/Data_Science/dataset/process_reviews2.py (3.5.3)
File Edit Format Run Options Window Help
import pandas as pd
import sys
from collections import Counter
import nltk
filename = sys.argv[1]
df = pd.read_json(filename, lines=True, encoding='utf-8')
print(df.head(5))
                                                                  But these
wtoks = ' '.join(df['text']).split()
                                                                 frequency
bigrams = nltk.bigrams(wtoks)
                                                               counter objects
trigrams = nltk.trigrams(wtoks)
                                                                 will take up
bifreq = Counter(bigrams)
                                                                   space.
print(bifreq.most common(20))
trifreq = Counter(trigrams)
print(trifreq.most common(20))
```

Generator type objects take up little memory space; meant to be used in a loop-like environment.

Content has been exhausted

```
>>> import nltk
>>> sent = 'Colorless green ideas sleep oh so very furiously'
>>> toks = sent.split()
>>> toks
['Colorless', 'green', 'ideas', 'sleep', 'oh', 'so', 'very', 'furiously']
>>> bigrams = nltk.bigrams(toks)
>>> bigrams
<generator object bigrams at 0x00000236371E2BF8>
>>> for b in bigrams:
        print(b)
('Colorless', 'green')
('green', 'ideas')
('ideas', 'sleep')
('sleep', 'oh')
('oh', 'so')
('so', 'very')
('very', 'furiously')
                                                                   Casting as list.
>>> bigrams
                                                              If you store the returned
<generator object bigrams at 0x00000236371E2BF8>
>>> list(bigrams)
                                                                  list, it will take up
                                                                   memory space.
>>> bigrams = nltk.bigrams(toks)
>>> list(bigrams)
[('Colorless', 'green'), ('green', 'ideas'), ('ideas', 'sleep'), ('sleep', 'oh')
, ('oh', 'so'), ('so', 'very'), ('very', 'furiously')]
>>>
```

File opening & closing methods

```
f = open('review.json')
lines = f.readlines()
for l in lines:
    if 'horrible' in l:
        print(l)
f.close()
```

```
f = open('review.json')
for l in f:
    if 'horrible' in l:
        print(l)
f.close()
```

```
with open('review.json') as f:
    for l in f:
        if 'horrible' in l:
            print(l)
```

Which methods are memory-efficient?

No need to close f later. Some folks swear by using with.

Handling files in chunks

```
f = open('review.json')
lines1 = f.readlines(1000000000)
lines2 = f.readlines(1000000000)
lines3 = f.readlines(1000000000)
lines4 = f.readlines(1000000000)
lines5 = f.readlines()
```

Optional # of bytes to read.

(When used like this without a loop, offers no memory advantage.)

Generator object. Takes up zero space.

```
dfs = pd.read_json('review.json', lines=True, chunksize=10000, encoding='utf8')
wfreq = Counter()
                                                     chunksize optional
for df in dfs:
                                                    parameter in pandas'
    wtoks = ' '.join(df['text']).split()
                                                 read json method reads in
    temp = Counter(wtoks)
                                                    10,000 lines at a time...
    wfreq.update(temp)
                                        then, iterate
print(wfreq.most common(20))
                                                              Memory-efficient!
                                        through each
                                                             This code uses only
                                          small df.
                                                            290MB of memory!!
```

Pandas vs. large data: tips

- "Why and How to Use Pandas with Large (but not big) Data"
 - https://towardsdatascience.com/why-and-how-to-use-pandas-with-large-data-9594dda2ea4c
- 1. Read CSV file data in chunk size
- 2. Filter out unimportant columns in DF to save memory
- 3. Change dtypes for columns
 - float64 takes up more space than float32.

Vectorizing and training in chunks

```
from sklearn.naive bayes import MultinomialNB
                                                                                      If vectorizer/ML model
from sklearn.feature extraction.text import HashingVectorizer
                                                                                    depends only on individual
import warnings
warnings.filterwarnings("ignore", category=DeprecationWarning)
                                                                                       row of data, it can be
                                                                                      implemented in chunks.
filename = 'review 10k.json'
length = 10000
                                                                                    (Caveat: TF-IDF vectorizer and
chunk size = 1000
                                                                                       most ML models can't.)
chunks = length/chunk size
df_chunks = pd.read_json(filename, lines=True, chunksize=chunk_size, encoding="utf-8")
clf = MultinomialNB()
                                                                                        Hashtag vectorizer
vectorizer = HashingVectorizer(non negative=True)
                                                                                    skips the IDF part of TF/IDF,
                                                                                  can be implemented in chunks!
for i, df in enumerate(df chunks):
   if i < 0.8 * chunks:
       clf.partial_fit(vectorizer.transform(df['text']), df['stars'], classes=[1,2,3,4,5])
    else:
        pred = clf.predict(vectorizer.transform(df['text']))
                                                                                            NB classifier can be
        print('batch {}, {} accuracy'.format(i, np.mean(pred == df['stars'])))
                                                                                           trained in partial bits!
```

batch 8, 0.444 accuracy batch 9, 0.439 accuracy

Computational efficiency: space vs. time

SPACE: **memory** footprint

- Do not create duplicate data objects.
- Avoid creating a data object that does not need to be stored in its entirety.
- In code, delete large data objects that will no longer be used
 - Do not simply rely on Python's garbage collection

TIME: processor runtime

- Avoid duplicating an expensive processing step: process once, store result as an object, then reuse.
- Use an efficient algorithm.
- Use the data type optimal for the task at hand.

Optimize both.

Trade-off relationship sometimes: manage available computational resources, achieve balance & goal!

Data types and optimization

```
[1]: import nltk
     nltk.data.path.append('/zfs2/ling1340-2019s/shared data/nltk data')

"Alice in Wonderland", 34K tokens

Task: find Alice words that are not found in enable list

Try 1: list-comprehend through awords (list), filter against enable (list)

```
[5]: %time notfound = [w for w in awords if w not in enable]
```

Try 2: same, but filter against enable list as a SET

```
[6]: enable_set = set(enable) # this one is a set data type
    print(len(enable_set)) # same size

172820

[7]: %time notfound = [w for w in awords if w not in enable_set]
```

▶ Try 3: compute the SET difference

```
[8]: awords_set = set(awords)
print(len(awords_set)) # now a set, smaller size
3016

[9]: %time notfound = awords_set.difference(enable_set)
```

Try 1: list-comprehend through awords (list), filter against enable (list)

```
[5]: %time notfound = [w for w in awords if w not in enable]

CPU times: user 39.7 s, sys: 16.2 ms, total: 39.7 s
Wall time: 39.8 s
```

Try 2: same, but filter against enable list as a SET

```
[6]: enable_set = set(enable) # this one is a set data type
    print(len(enable_set)) # same size

172820

[7]: %time notfound = [w for w in awords if w not in enable_set] much
    CPU times: user 20.3 ms, sys: 4 ms, total: 24.3 ms
    Wall time: 24.8 ms
```

▶ Try 3: compute the SET difference

```
[8]: awords_set = set(awords)
print(len(awords_set)) # now a set, smaller size

3016

[9]: %time notfound = awords_set.difference(enable_set)
CPU times: user 332 μs, sys: 2 μs, total: 334 μs
Wall time: 339 μs
fast
```

List as a data type is NOT optimized for membership operations...

but **set** is!

Keep efficiency in mind, pick right combination of data structure and operation

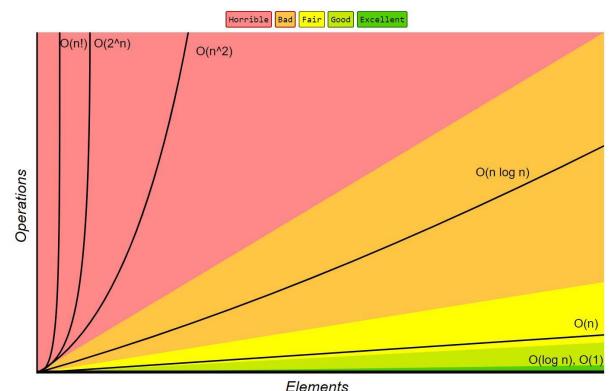

Algorithmic complexity and the Big O

- https://rob-bell.net/2009/06/a-beginners-guide-to-big-o-notation/
- ▶ We have a **list of** *n* **items**. Imagine *n* is 100, 1000 or even 1 million.
- 1. Is the first element an even number?
 - Can be implemented in O(1): an algorithm that executes in a **constant** time regardless of the size of the input dataset.
- 2. Does the list contain value 42?
 - Can be implemented in O(n): an algorithm whose performance will grow linearly in proportion to the size of the input data.
- 3. Does the list contain duplicate values?
 - Can be implemented in O(n²):an algorithm whose performance is directly proportional to the square of the size of the input data set (quadratic).

Algorithmic complexity and the Big O

- https://rob-bell.net/2009/06/a-beginners-guide-to-big-o-notation/
- ▶ We have a **list of** *n* **items**. Imagine *n* is 100, 1000 or even 1 million.
- 4. Sort the list (ascending or descending)
 - Can be implemented in O(n log n): an algorithm that executes in loglinear time.
 - See: https://brilliant.org/wiki/sorting-algorithms/

3/26/2019

Big-O Complexity Chart

http://bigocheatsheet.com/

Algorithmic efficiency: summary

- ▶ A problem can be implemented with varying degrees of algorithmic efficiency.
- A problem comes with its own inherent algorithmic complexity limit.
 - **Big O notation** is a mathematical notation that encapsulates the relationship between the processing time and the input data size.
 - Example: the most efficient known sorting algorithm bottoms out at O(n log n).

In a nutshell...

- Compose the most efficient algorithm that you can.
- Understand the relationship between the data size growth and the processing time growth. O(n) has fair scalability, O(n²) becomes intractable.
- Efficiency of an algorithm can lead to dramatic runtime difference when dealing with big data.

Word embeddings

→ Dan's slides

Wrapping up

Homework 4

- Fun with CRC!
- Make sure to check out the list of tips at the bottom of the page...
- As a class we have 10000 Service Units, which is 10k hours of computing time (not that much).
 - Don't let your jobs run infinitely! Test on small samples of data and make sure they work before you run large jobs.
